

VG101 — Introduction to Computer and Programming

Assignment 8 (13/12/2016)

Manuel — UM-JI (Fall 2016)

- Write each exercise in a different file
- Include simple comments in the code
- If applicable, split the implementation over several functions
- Write a single README file per assignment
- Archive all the files in a zip file and upload it onto Sakai

Project instructions

The goal of this project is to better understand Object Oriented Programming. In particular Classes, Inheritance, and Polymorphism are at the core of the project and must be applied in order to complete it. It is highly recommended to:

- Start thinking of the project as early as possible;
- Focus mainly on the organisation at the beginning;
- Define various objects and relate them to each others;

In this project many questions are left to the appreciation of the programmers. Based on your knowledge, research, and understanding argue on your choices in the README file.

The project splits into two parts: (i) the design of a generic parking lot, and (ii) the drawing of an interstellar parking lot using the OpenGL library. The two part should be written independently and be provided with their respective compiling commands.

A paper form will be provided for each student to briefly explain his contribution to the project.

Remark: do not exchange code among groups; Honor Code will be strictly applied.

Part I – A generic parking lot

In a software engineering company you are asked to design a software to manage a car park. Although several discussions with the customer have lead to some basic specifications much flexibility is left to you. In order to show the customer how the program performs write a simulation where random vehicles enter and exit the parking lot over a given period of time.

Basic specifications

- Parking area: more than one floor, each one being of different size
- Vehicles: van, car, motorbike, bicycle
- Price: depends on the type of vehicle and time spent
- Arrival ticket: when a user arrives he receives a ticket containing:
 - Time of arrival
 - Type of the vehicle
 - Some information (hint) on where to find an empty slot
- Departure ticket: when a user leaves he receives a ticket containing:
 - Time spent in the parking lot
 - Type of vehicle
 - Price

Part II – An interstellar parking lot

The goal of this part is to use OpenGL to design an interstellar parking lot and drive a car into a free slot. The parking should be composed of at least ten slots, among which at least one is free. A slot that is not empty can be:

- Reserved for teleported vehicles. Such a slot contains a rectangle which randomly changes color;
- Occupied by a UFO which spins on itself;
- Occupied by a spacecraft which continuously zooms in and out;

The number of vehicles of each type as well as the amount of reserved slots is randomly set. In this initial setup the car is waiting in front of the barrier. Once open, the car follows a smooth trajectory to a free slot. The car should only stop *after* the empty space and reverse into the slot following a smooth curve. An example of such trajectories is drawn in blue and red on Fig. 1.

Figure 1: Interstellar car park: initial setup example

This part of the project being more complex it is advised to comply with the following guidelines.

- Define a clear hierarchy to organise the various objects (a partial version is provided on Fig. 2);
- Complete the partial classes interface provided below:
 - The Vec class defines a mathematical vector; The class should be immutable, i.e. no method is allowed to change any attribute at any time, but construction; It is intended for instance to define points without dealing with each coordinate;
 - The figure class defines a central point called anchor around which the figure can rotate, or zoom. Other methods are also listed;
 - The Group class inherits from Figure and as such is a figure. It is however composed of other “sub-figures”, and as such can contain other Group;
- All the attributes should be either private or protected
- STL vectors can be used to store objects;

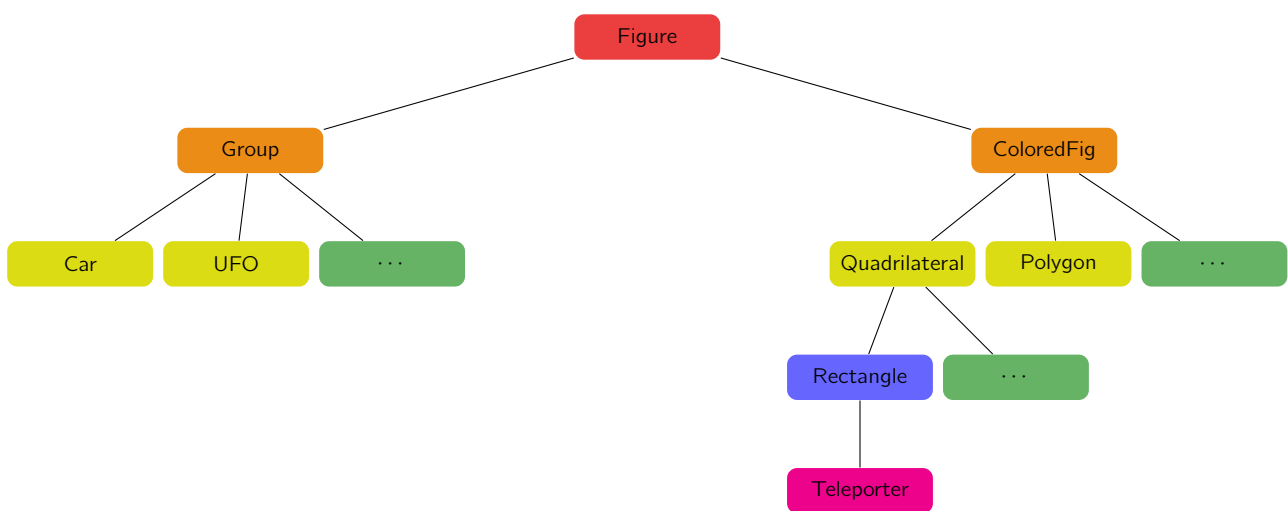

Figure 2: Partial interstellar parking slot hierarchy

Partial classes interface

```
1 class Vec {
2 private:
3     float x,y;
4 public:
5     Vec(float _x, float _y) {
6         x = _x; y = _y;
7     }
8     float getX() {return x;}
9     float getY() {return y;}
10
11     // Example Overloads + operator
12     // returns the sum of 2 Vec
13     Vec operator+ (Vec v) {
14         return Vec(x + v.getX(), y + v.getY());
15     }
16 }
```

```

17 // Overload - on 2 Vectors
18 // return thier difference Vector
19
20 // Overload * operator on a float k
21 // return current Vector scaled by k
22
23 // Overload * on 2 Vectors
24 // return thier inner product (scaler product)
25
26 // Overload << on an angle
27 // return current vector rotated counter clockwise
28 // by this angle
29
30 // Overload >> on an angle
31 // return current vector rotated clockwise
32 // by this angle
33 };
34
35 class Figure {
36 protected:
37     Vec anchor;
38 public:
39     Figure() : anchor(0, 0) {}
40
41     Vec getAnchor() {return anchor;}
42     void setAnchor(Vec a) {anchor = a;}
43     virtual void draw() = 0;
44     virtual void move(Vec dir) = 0;
45     virtual void rotate(float angle) = 0;
46     virtual void zoom(float k) = 0;
47
48     virtual ~Figure() {}
49 }
50
51 class Group : Figure {
52 private:
53     // A Group of figure "has" other figures.
54 public:
55
56     // We left out the constructor as well
57
58     void draw(); // Draw out all its figures
59     void move(Vec dir); // Move all its figures
60     void rotate(float angle); // Rotate the group as a whole.
61     void zoom(float k); // Zoom the group as a whole.
62     ~Group() {}
63 }

```

More advanced strategy

While applying the following advice is not mandatory, it can greatly help in the design of a clean project.

As the use of global variables is forbidden it is tempting to “abuse” static variables. However a cleaner way is to implement a Singleton class. A singleton is a clean way to ensure an object is not instantiated more than once. This could be useful for instance in the `glDraw` function.

More information on singleton can be found in the following resources:

- https://en.wikipedia.org/wiki/Singleton_pattern
- <http://www.yolinux.com/TUTORIALS/C%2B%2BSingleton.html>
- <http://stackoverflow.com/questions/1008019/c-singleton-design-pattern>

Minimal Singleton class implementation

```
1 class Singleton {
2     private:
3         Singleton() {};
4         ~Singleton() {};
5         // omit copy constructor
6         // omit overloading assignment operator
7
8     Public:
9         static Singleton* getInstance() {
10             Static Singleton *s = NULL;
11             if (s != NULL) s = new Singleton();
12             return s;
13         }
14
15         Static void deleteInstance() {
16             Singleton *s = Singleton::getInstance();
17             if (s != NULL) delete s;
18             s = NULL;
19         }
20
21 };
```
